32-BIT QUADRATURE COUNTER WITH SERIAL INTERFACE

June 2014

GENERAL FEATURES:

- Operating voltage: 3V to 5.5V ($V_{DD} - V_{SS}$)
 - 5V count frequency: 40MHz
 - 3V count frequency: 20MHz
 - 32-bit counter (CNTR).
 - 32-bit data register (DTR) and comparator.
 - 32-bit output register (OTR).
 - Two 8-bit mode registers (MDR0, MDR1) for programmable functional modes.
 - 8-bit instruction register (IR).
 - 8-bit status register (STR).
 - Latched Interrupt output on Carry or Borrow or Compare or Index.
 - Index driven counter load, output register load or counter reset.
 - Internal quadrature clock decoder and filter.
 - x1, x2 or x4 mode of quadrature counting.
 - Non-quadrature up/down counting.
 - Modulo-N, Non-recycle, Range-limit or Free-running modes of counting
 - 8-bit, 16-bit, 24-bit and 32-bit programmable configuration synchronous (SPI) serial interface
 - **LS7366R** (DIP), **LS7366R-S** (SOIC), **LS7366R-TS** (TSSOP)
- See Figure 1 -

SPI/MICROWIRE (Serial Peripheral Interface):

- Standard 4-wire connection: MOSI, MISO, SS/ and SCK.
- Slave mode only.

GENERAL DESCRIPTION:

LS7366R is a 32-bit CMOS counter, with direct interface for quadrature clocks from incremental encoders. It also interfaces with the index signals from incremental encoders to perform variety of marker functions.

For communications with microprocessors or microcontrollers, it provides a 4-wire SPI/MICROWIRE bus. The four standard bus I/Os are SS/, SCK, MISO and MOSI. The data transfer between a microcontroller and a slave LS7366R is synchronous. The synchronization is done by the SCK clocks supplied by the microcontroller. Each transmission is organized in blocks of 1 to 5 bytes of data. A transmission cycle is initiated by a high to low transition of the SS/ input. The first byte received in a transmission cycle is always an instruction byte, whereas the second through the fifth bytes are always interpreted as data bytes. A transmission cycle is terminated with the low to high transition of the SS/ input. Received bytes are shifted in at the MOSI input, MSB first, with the leading edges (high transition) of the SCK clocks. Output data are shifted out on the MISO output, MSB first, with the trailing edges (low transition) of the SCK clocks.

PIN ASSIGNMENT
TOP VIEW

FIGURE 1

Read and write commands cannot be combined. For example, when the device is shifting out read data on MISO output, it ignores the MOSI input, even though the SS/ input is active. SS/ must be terminated and reasserted before the device will accept a new command.

The counter can be configured to operate as 1, 2, 3 or 4-byte counter. When configured as an n-byte counter, the CNTR, DTR and OTR are all configured as n-byte registers, where $n = 1, 2, 3$ or 4 .

The content of the instruction/data identity is automatically adjusted to match the n-byte configuration. For example, if the counter is configured as a 2-byte counter, the instruction "write to DTR" expects 2 data bytes following the instruction byte. If the counter is configured as a 3-byte counter, the same instruction will expect 3 bytes of data following the instruction byte.

Following the transfer of the appropriate number of bytes any further attempt of data transfer is ignored until a new instruction cycle is started by switching the SS/ input to high and then low.

The counter can be programmed to operate in a number of different modes, with the operating characteristics being written into the two mode registers MDR0 and MDR1. Hardware I/Os are provided for event driven operations, such as processor interrupt and index related functions.

I/O Pins:

Following is a description of all the input/output pins.

A (Pin 12) B (Pin 11)

Inputs. A and B quadrature clock outputs from incremental encoders are directly applied to the A and B inputs of the LS7366R. These clocks are ideally 90 degrees out-of-phase signals. A and B inputs are validated by on-chip digital filters and then decoded for up/down direction and count clocks. In non-quadrature mode, A serves as the count input and B serves as the direction input (B = high enables up count, B = low enables down count). In non-quadrature mode, the A and B inputs are not filtered internally, and are instantaneous in nature.

INDEX/ (Pin 10)

Input. The INDEX/ is a programmable input that can be driven directly by the Index output of an incremental encoder. It can be programmed via the MDR0 to function as one of the following:

LCNTR (load CNTR with data from DTR), RCNTR (reset CNTR), or LOTR (load OTR with data from CNTR). Alternatively, the INDEX input can be masked out for "no functionality".

In quadrature mode, the INDEX/ input can be configured to operate in either synchronous or asynchronous mode. In the synchronous mode the INDEX/ input is sampled with the same filter clock used for sampling the A and the B inputs and must satisfy the phase relationship in which the INDEX/ is in the active level of Logic 0 during a minimum of a quarter cycle of both A and B High or both A and B Low. In non-quadrature mode, the INDEX/ input is unconditionally set to the asynchronous mode. In the asynchronous mode, the INDEX/ input is not sampled and can be applied in any phase relationship with respect to A and B.

fcki (Pin 2), fcko (Pin 1)

Input, Output. A crystal connected between these 2 pins generates the basic clock for filtering the A, B and INDEX/ inputs in the quadrature count mode. Instead of a crystal the fcki input may also be driven by an external clock.

The frequency at the fcki input is either divided by 2 (if MDR0 <B7> = 1) or divided by 1 (if MDR0 <B7> = 0) for the filter circuit. For proper filtering of the A, B and the Index/ inputs the following condition must be satisfied:

$$f_i \geq 4f_{QA}$$

Where f_i is the internal filter clock frequency derived from the fcki in accordance with the status of MDR0 <B7> and f_{QA} is the maximum frequency of Clock A in quadrature mode. In non-quadrature count mode, fcki is not used and should be tied off to any stable logic state.

SS/ (Pin 4)

A high to low transition at the SS/ (Slave Select) input selects the LS7366R for serial bi-directional data transfer; a low to high transition disables serial data transfer and brings the MISO output to high impedance state. This allows for the accommodation of multiple slave units on the serial I/O.

CNT_EN (Pin 13)

Input. Counting is enabled when CNT_EN input is high; counting is disabled when this input is low. There is an internal pull-up resistor on this input.

LFLAG/ (Pin 8), DFLAG/ (Pin 9)

Outputs. LFLAG/ and DFLAG/ are programmable outputs to flag the occurrences of Carry (counter overflow), Borrow (counter underflow), Compare (CNTR = DTR) and INDEX. The LFLAG/ is an open drain latched output. In contrast, the DFLAG/ is a push-pull instantaneous output. The LFLAG/ can be wired in multi-slave configuration, forming a single processor interrupt line. When active LFLAG/ switches to logic 0 and can be restored to the high impedance state only by clearing the status register, STR. In contrast, the DFLAG/ dynamically switches low with occurrences of Carry, Barrow, Compare and INDEX conditions.

The configuration of LFLAG/ and DFLAG/ are made through the control register MDR1.

MOSI (RXD) (Pin 7)

Input. Serial output data from the host processor is shifted into the LS7366R at this input.

MISO (TXD) (Pin 6)

Output. Serial output data from the LS7366R is shifted out on the MISO (Master In Slave Out) pin. The MISO output goes into high impedance state when SS/ input is at logic high, providing multiple slave-unit serial outputs to be wire-ORed.

SCK (Pin 5)

Input. The SCK input serves as the shift clock input for transmitting data in and out of LS7366R on the MOSI and the MISO pins, respectively. Since the LS7366R can operate only in the slave mode, the SCK signal is provided by the host processor as a means for synchronizing the serial transmission between itself and the slave LS7366R.

REGISTERS:

The following is a list of LS7366R internal registers:

Upon power-up the registers DTR, CNTR, STR, MDR0 and MDR1 are reset to zero.

DTR. The DTR is a software configurable 8, 16, 24 or 32-bit input data register which can be written into directly from MOSI, the serial input. The DTR data can be transferred into the 32-bit counter (CNTR) under program control or by hardware index signal. The DTR can be cleared to zero by software control. In certain count modes, such as modulo-n and range-limit, DTR holds the data for "n" and the count range, respectively. In compare operations, whereby compare flag is set, the DTR is compared with the CNTR.

The information included herein is believed to be accurate and reliable. However, LSI Computer Systems, Inc. assumes no responsibilities for inaccuracies, nor for any infringements of patent rights of others which may result from its use.

CNTR. The CNTR is a software configurable 8, 16, 24 or 32-bit up/down counter which counts the up/down pulses resulting from the quadrature clocks applied at the A and B inputs, or alternatively, in non-quadrature mode, pulses applied at the A input. By means of IR instructions the CNTR can be cleared, loaded from the DTR or in turn, can be transferred into the OTR.

OTR. The OTR is a software configuration 8, 16, 24 or 32-bit register which can be read back on the MISO output. Since instantaneous CNTR value is often needed to be read while the CNTR continues to count, the OTR serves as a convenient dump site for instantaneous CNTR data which can then be read without interfering with the counting process.

STR. The STR is an 8-bit status register which stores count related status information.

CY	BW	CMP	IDX	CEN	PLS	U/D	S
7	6	5	4	3	2	1	0

CY: Carry (CNTR overflow) latch

BW: Borrow (CNTR underflow) latch

CMP: Compare (CNTR = DTR) latch

IDX: Index latch

CEN: Count enable status: 0: counting disabled,
1: counting enabled

PLS: Power loss indicator latch; set upon power up

U/D: Count direction indicator: 0: count down, 1: count up

S: Sign bit. 1: negative, 0: positive

IR. The IR is an 8-bit register that fetches instruction bytes from the received data stream and executes them to perform such functions as setting up the operating mode for the chip (load the MDR) and data transfer among the various registers.

B7	B6	B5	B4	B3	B2	B1	B0
----	----	----	----	----	----	----	----

B2 B1 B0 = XXX (Don't care)

B5 B4 B3 = 000: Select none

= 001: Select MDR0

= 010: Select MDR1

= 011: Select DTR

= 100: Select CNTR

= 101: Select OTR

= 110: Select STR

= 111: Select none

B7 B6 = 00: CLR register

= 01: RD register

= 10: WR register

= 11: LOAD register

The actions of the four functions, CLR, RD, WR and LOAD are elaborated in Table 1.

TABLE 1			
Number of Bytes	OP Code	Register	Operation
1	CLR	MDR0	Clear MDR0 to zero
		MDR1	Clear MDR1 to zero
		DTR	None
		CNTR	Clear CNTR to zero
		OTR	None
		STR	Clear STR to zero
2 to 5	RD	MDR0	Output MDR0 serially on TXD (MISO)
		MDR1	Output MDR1 serially on TXD (MISO)
		DTR	None
		CNTR	Transfer CNTR to OTR, then output OTR serially on TXD (MISO)
		OTR	Output OTR serially on TXD (MISO)
		STR	Output STR serially on TXD (MISO)
2 to 5	WR	MDR0	Write serial data at RXD (MOSI) into MDR0
		MDR1	Write serial data at RXD (MOSI) into MDR1
		DTR	Write serial data at RXD (MOSI) into DTR
		CNTR	None
		OTR	None
1	LOAD	STR	None
		MDR0	None
		MDR1	None
		DTR	None
		CNTR	Transfer DTR to CNTR in "parallel"
		OTR	Transfer CNTR to OTR in "parallel"

MDR0. The MDR0 (Mode Register 0) is an 8-bit read/write register that sets up the operating mode for the LS7366R. The MDR0 is written into by executing the "write-to-MDR0" instruction via the instruction register. Upon power up MDR0 is cleared to zero. The following is a breakdown of the MDR bits:

B7	B6	B5	B4	B3	B2	B1	B0
----	----	----	----	----	----	----	----

- B1 B0 = 00: non-quadrature count mode. (A = clock, B = direction).

= 01: x1 quadrature count mode (one count per quadrature cycle).

= 10: x2 quadrature count mode (two counts per quadrature cycle).

= 11: x4 quadrature count mode (four counts per quadrature cycle).
- B3 B2 = 00: free-running count mode.

= 01: single-cycle count mode (counter disabled with carry or borrow, re-enabled with reset or load).

= 10: range-limit count mode (up and down count-ranges are limited between DTR and zero, respectively; counting freezes at these limits but resumes when direction reverses).

= 11: modulo-n count mode (input count clock frequency is divided by a factor of (n+1), where n = DTR, in both up and down directions).
- B5 B4 = 00: disable index.

= 01: configure index as the "load CNTR" input (transfers DTR to CNTR).

= 10: configure index as the "reset CNTR" input (clears CNTR to 0).

= 11: configure index as the "load OTR" input (transfers CNTR to OTR).
- B6 = 0: Asynchronous Index

= 1: Synchronous Index (overridden in non-quadrature mode)
- B7 = 0: Filter clock division factor = 1

= 1: Filter clock division factor = 2

MDR1. The MDR1 (Mode Register 1) is an 8-bit read/write register which is appended to MDR0 for additional modes. Upon power-up MDR1 is cleared to zero.

B7	B6	B5	B4	B3	B2	B1	B0
----	----	----	----	----	----	----	----

- B1 B0 = 00: 4-byte counter mode

= 01: 3-byte counter mode

= 10: 2-byte counter mode.

= 11: 1-byte counter mode
- B2 = 0: Enable counting

= 1: Disable counting
- B3 = : not used
- B4 = 0: NOP

= 1: FLAG on IDX (B4 of STR)
- B5 = 0: NOP

= 1: FLAG on CMP (B5 of STR)
- B6 = 0: NOP

= 1: FLAG on BW (B6 of STR)
- B7 = 0: NOP

= 1: FLAG on CY (B7 of STR)
- NOTE: Applicable to both LFLAG/ and DFLAG/

Note 1. The SPI port of the host MCU must be set up as follows:

1. SPI master mode.
2. SCK idle state = low
3. Clock edge for MOSI data shift = high to low
4. Clock edge for input data (MISO) sample by the Processor = low to high (or bit middle)

Note 2. To conform with the multibyte transmission protocol of LS7366R, the SS/ output port of the MCU may require direct manipulation by the application program.
